

# Fundamentals, Optimization and Practical Aspects of UHPLC

## Part 3

The Role of Temperature, Column Technology, Totally Porous and  
Superficially Porous Particles, Monoliths, Method Translation

# Role of Temperature in (U)HPLC

## Temperature increase

- Decrease in the mobile phase viscosity\*
  - Viscosity is reduced 1 to 2 % per °C increase
  - Lower back pressure
- Increase of solute diffusivity
  - Lower HETP-value
- Decrease in the mobile phase polarity
  - Increasing temperature 4 to 5 °C is comparable to increasing the methanol or acetonitrile concentration by 1% in a reversed phase system
  - Less organic solvent in the eluent (in RP separations)

$$D_{m,T} = D_{m,298} \frac{\eta_{298}}{\eta_T} \frac{T}{298}$$

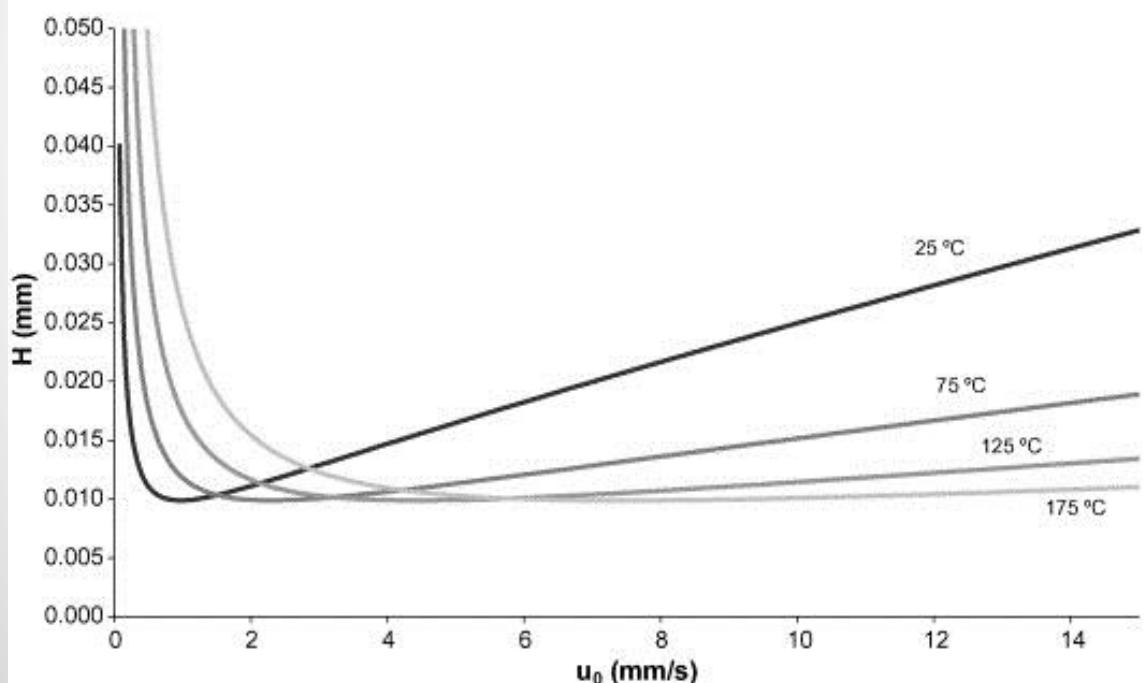

\*J. Billen et al., J. Chrom. A, 1210, 30 (2008)

# Role of Temperature in (U)HPLC

## Theoretical based on the Knox equation

Theoretical plate-height curves for 5 µm particles calculated with equation below assuming values of: A = 0.66, B = 3.00 and C = 0.05. Diffusion coefficients for phenol in 40/60 acetonitrile/water were calculated at each temperature according to Wilke-Chang

$$H = d_p \left[ A \left( \frac{u_0 d_p}{D_m} \right)^{1/3} + B \left( \frac{D_m}{u_0 d_p} \right) + C \left( \frac{u_0 d_p}{D_m} \right) \right]$$

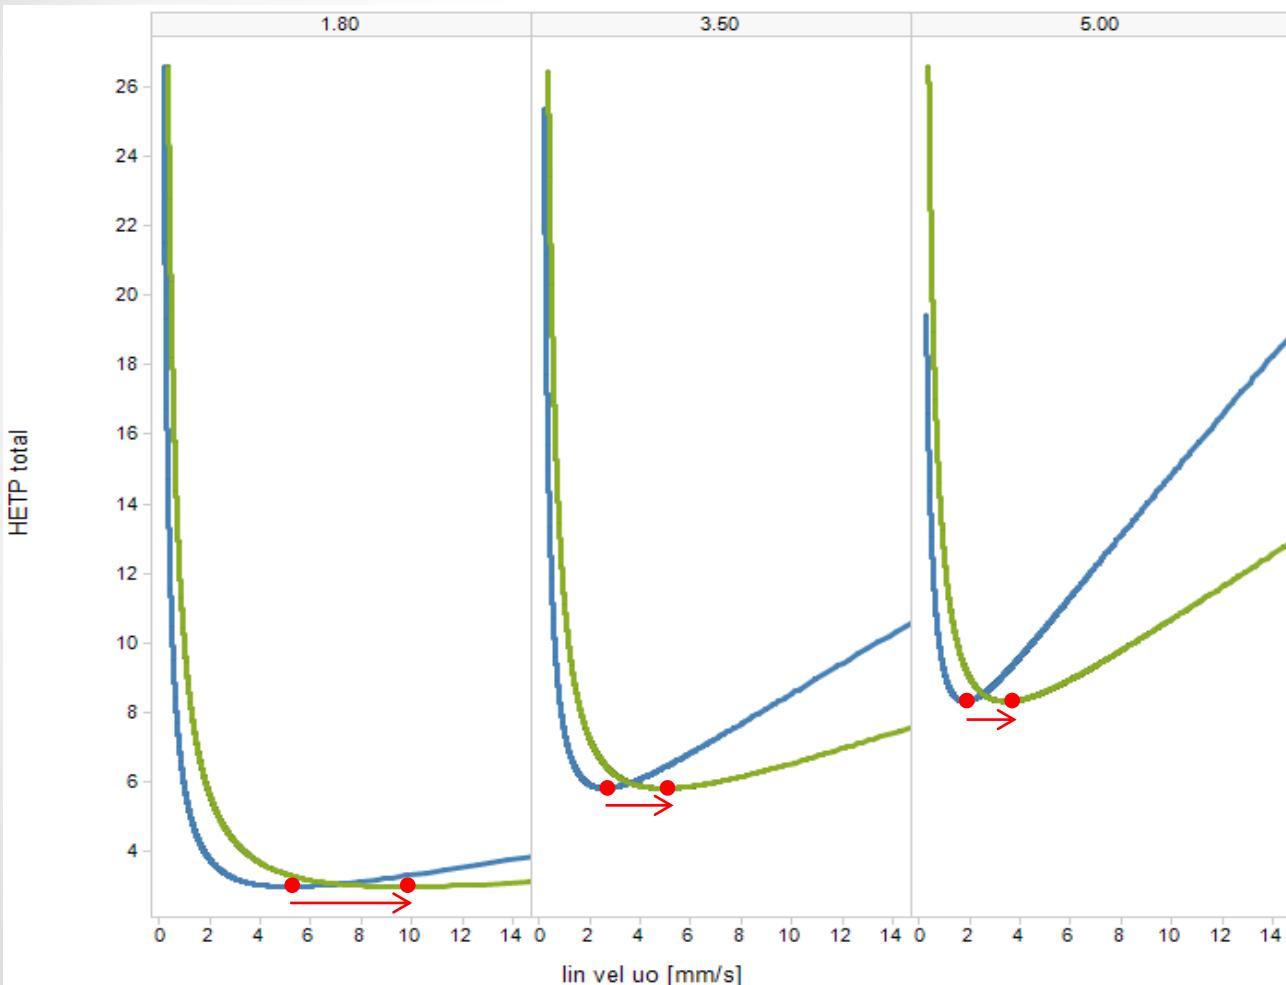

- a. Minimum in the HETP plot is not affected by temperature increase
- b. The C-term region flattens.

F. Lestremau et al., J. Chrom. A, 1138, 2007, 120 - 131

# Role of Temperature in (U)HPLC

## Theoretical based on the Knox equation

Color by Temperature °C  
40  
80

$$D_m \propto \frac{1}{\eta}$$

$$u_{opt} \propto D_m \propto \frac{1}{\eta}$$

$$\Delta P \propto u_{opt} \cdot \eta$$

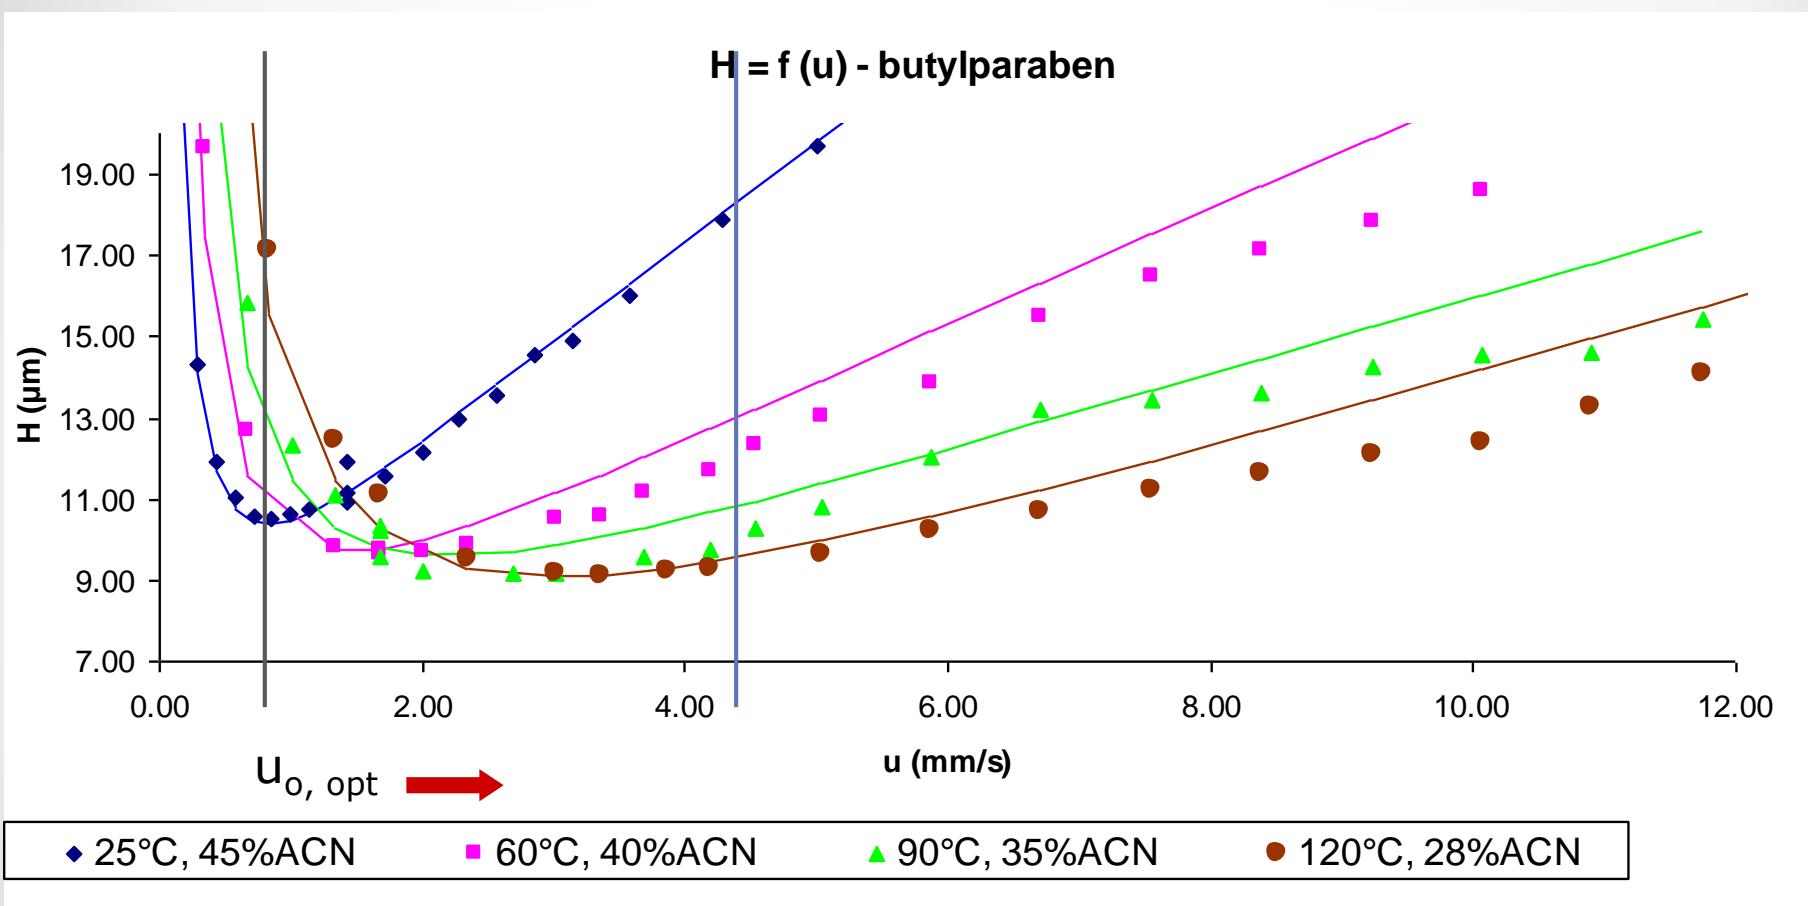

$H_{min}$  does not change with T

$u_{0,opt}$  increases with T

The pressure required to operate a column at  $u_{0,opt}$  does not change with temperature

# Role of Temperature in (U)HPLC

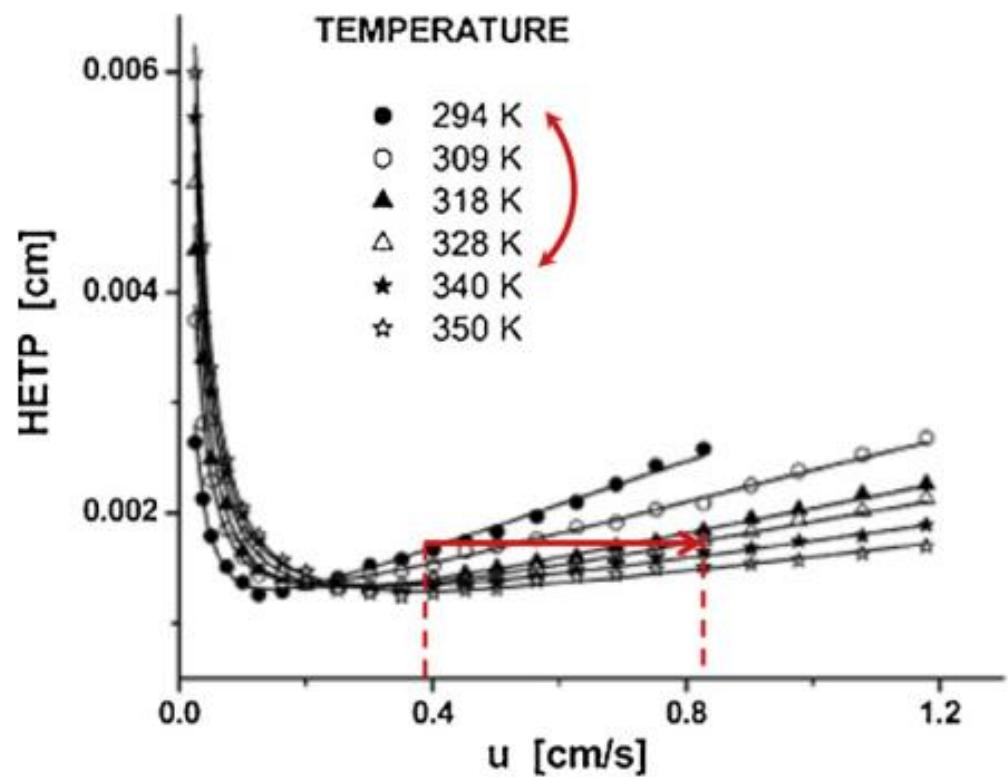

## Experimental Result\*

\*Results courtesy of Dr. Davy Guillarme, Univ. Geneva

# Role of Temperature in (U)HPLC

## Experimental Result\*

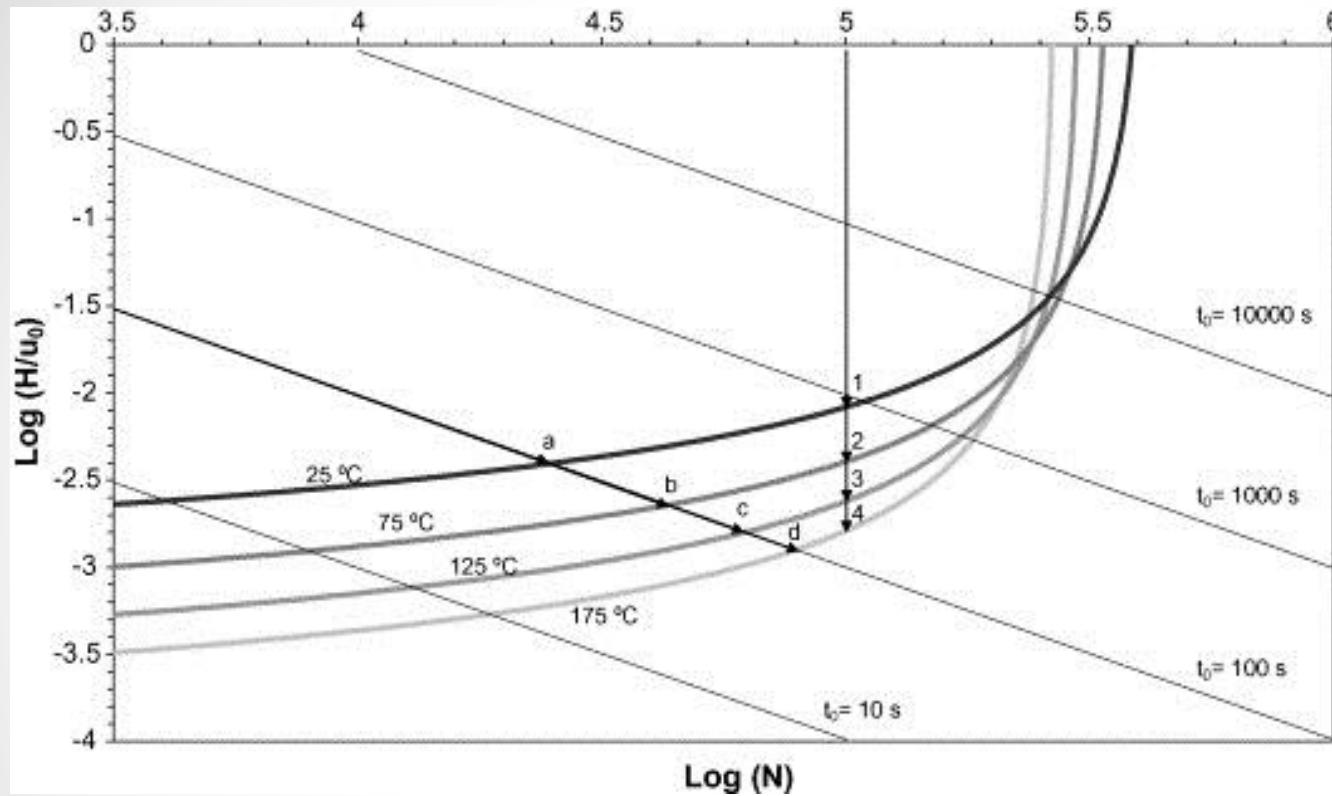

**Fig. 2.** Effect of the temperature on the HETP of a 5  $\mu\text{m}$  Sunfire-C<sub>18</sub> column for phenol eluted with a mixture of acetonitrile and water (15/85, v/v). The eluent viscosity decreases from 1.09 to 0.37 cP when the temperature increases from the ambient temperature to 77 °C.

\*Guiochon & Gritti, J. Chrom. A, 1228 2 (2012)

# Role of Temperature in UHPLC

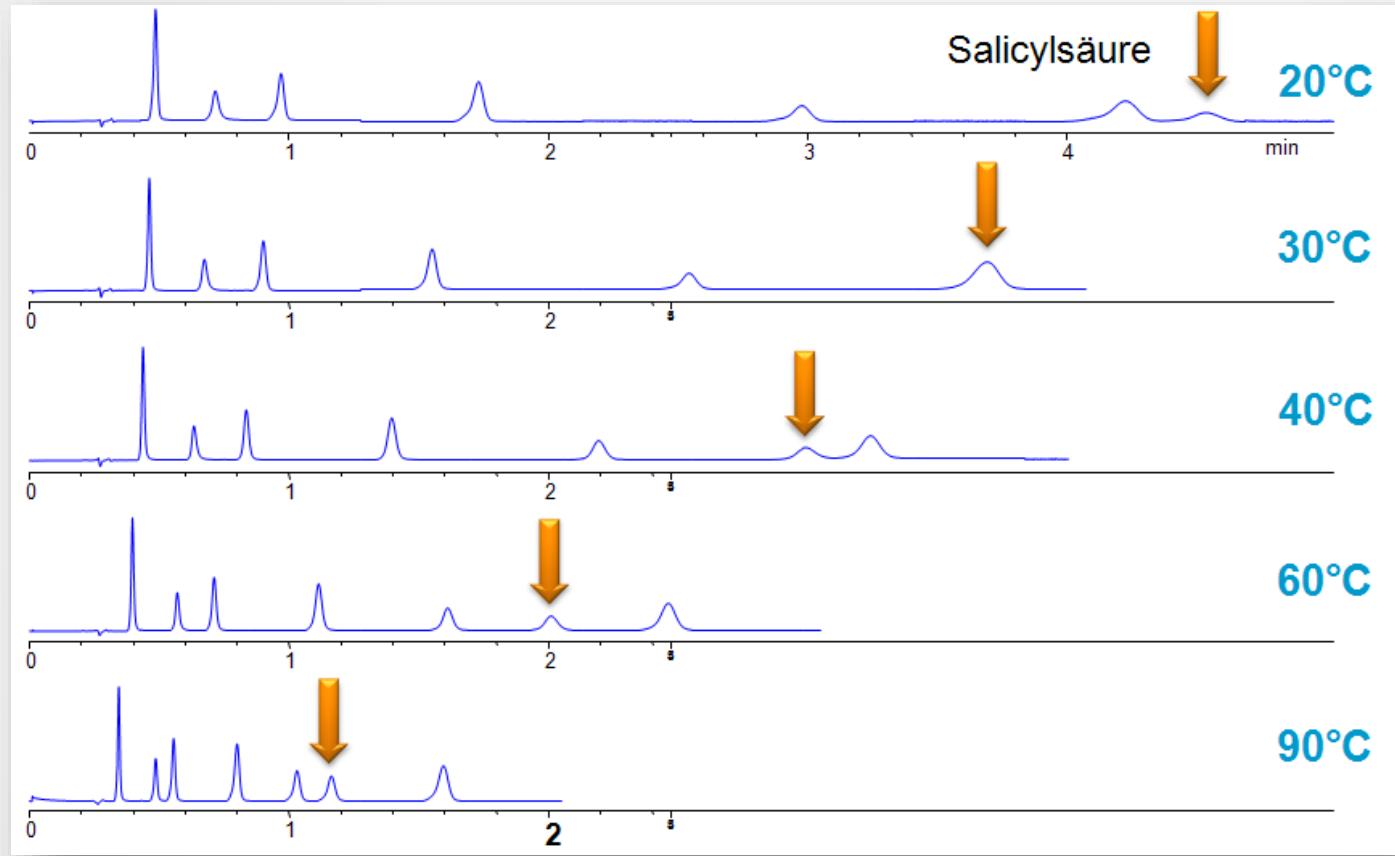

## Poppe Plot\*

Kinetic plots for 5  $\mu\text{m}$  particles at different temperatures (black: 25°C, dark grey: 75°C, grey: 125°C, light grey: 175°C). Assumed parameters: maximum pressure,  $P = 400$  bar; mobile phase 40/60 acetonitrile/water; viscosity,  $\eta = 8.28 \times 10^{-4}$  Pa s (25°C),  $4.11 \times 10^{-4}$  Pa s (75°C),  $2.44 \times 10^{-4}$  Pa s (125°C),  $1.62 \times 10^{-4}$  Pa s (175°C) calculated with flow resistance factor,  $\phi_0 = 1000$ ; diffusion coefficients,  $D_m = 1 \times 10^{-9}$  m<sup>2</sup>/s (25°C),  $2.35 \times 10^{-9}$  m<sup>2</sup>/s (75°C),  $4.54 \times 10^{-9}$  m<sup>2</sup>/s (125°C),  $7.68 \times 10^{-9}$  m<sup>2</sup>/s (175°C); Knox parameters: A = 0.66, B = 3.00 and C = 0.05.

# Role of Temperature in UHPLC

## Selectivity changes

Column: ZORBAX SB-C18 4.6 x 50 mm, 1.8  $\mu$ m

Solvent: A: Water + 0.1% formic acid B: Acetonitrile + 0.1% formic acid (85:15), Flowrate: 1 mL/min

Data and slide courtesy of Dr. Udo Huber, Agilent Technologies, Germany

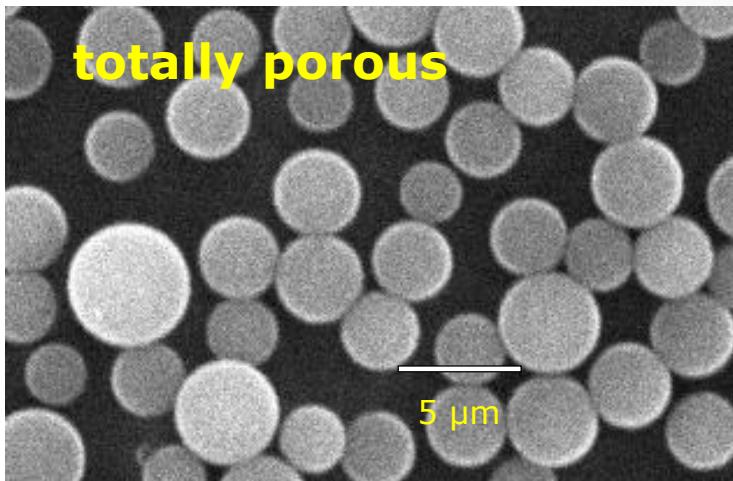

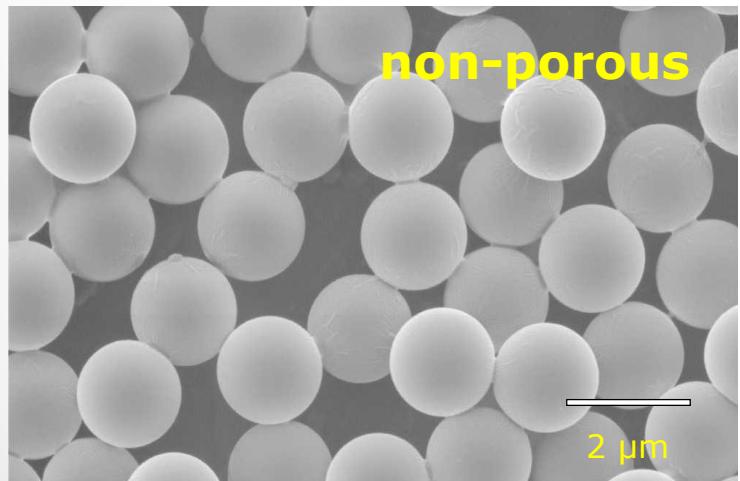

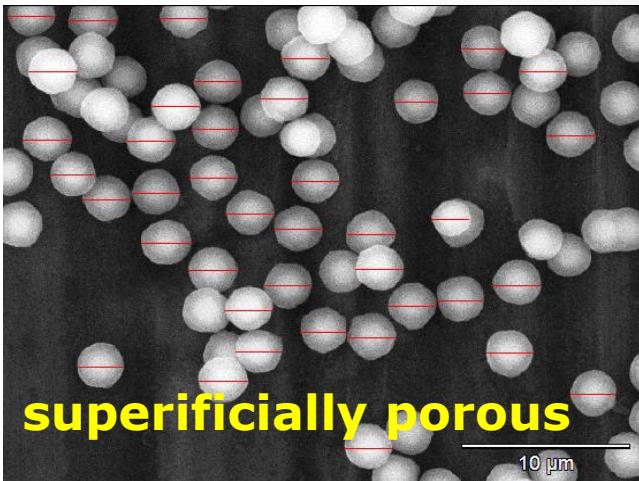

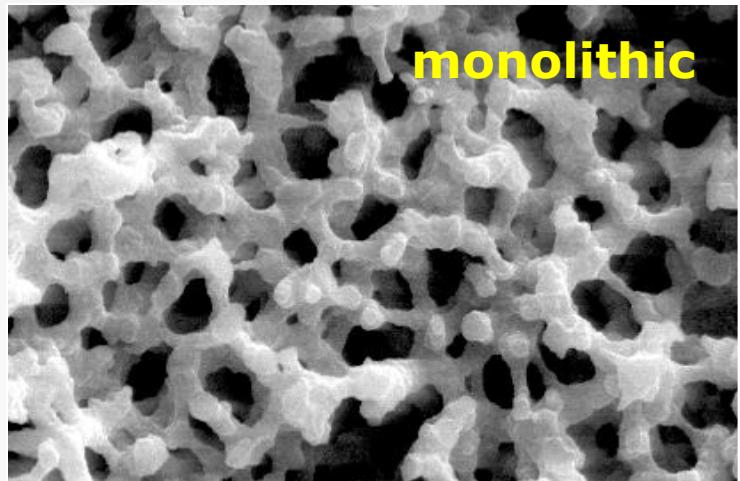

# Lessons learned about the role of temperature in UHPLC

- $u_{o,opt}$  increases with higher temperature which cancels the pressure reduction by the lower mobile phase viscosity.
- In case one operates at velocities higher than  $u_{o,opt}$  temperature increase will significantly reduce the HETP. Therefore, high temperature UHPLC allows to work at higher flow rate with gain in efficiency
- At higher temperature, the same retention factor is obtained with less organic solvent → “green” chromatography!
- Be aware of selectivity changes with temperature!
- Stability of the stationary phase will be an issue!
- Standard column thermostats are limited to 100 °C. Special heater required

# Column Technology for UHPLC

## Superficially Porous Particles

Superficially Porous Particles were introduced already in the 60ties by Cs. Horvath and modernized by J.J. Kirkland et al in the late 90ties (Poroshell 300) and in 2005 (Halo series)

The particle has 2.7  $\mu\text{m}$  outer diameter with a solid core (1.7  $\mu\text{m}$ ) and porous outer layer with a 0.5  $\mu\text{m}$  diffusion path. The average pore diameter is 120 Å. The core has 25% of the particle volume. 75% of the particle volume is porous. (Poroshell 120)

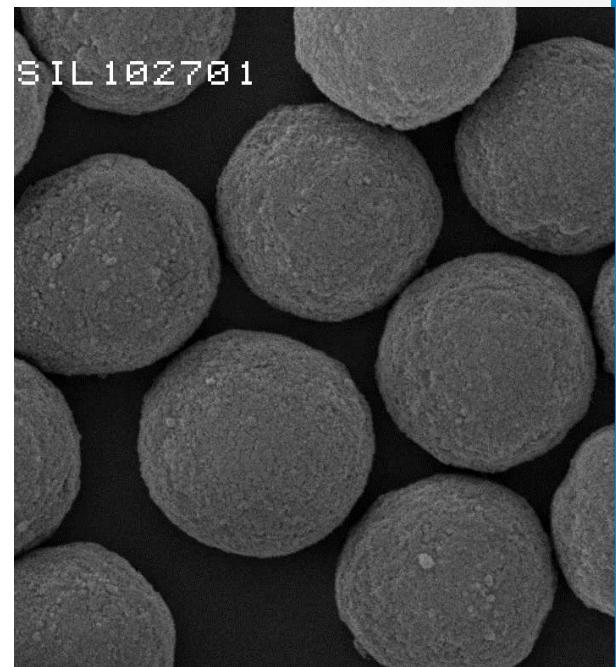

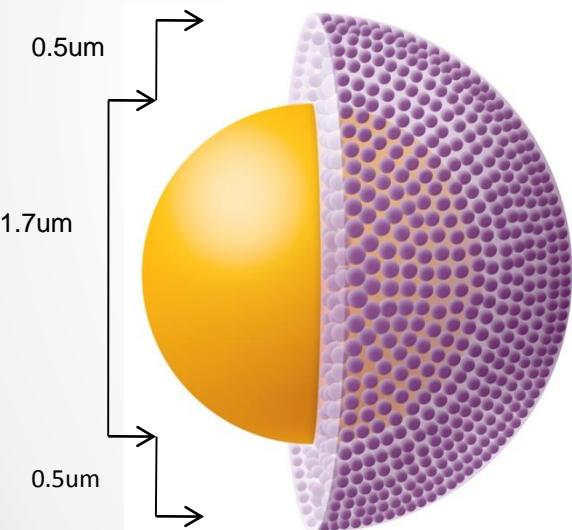

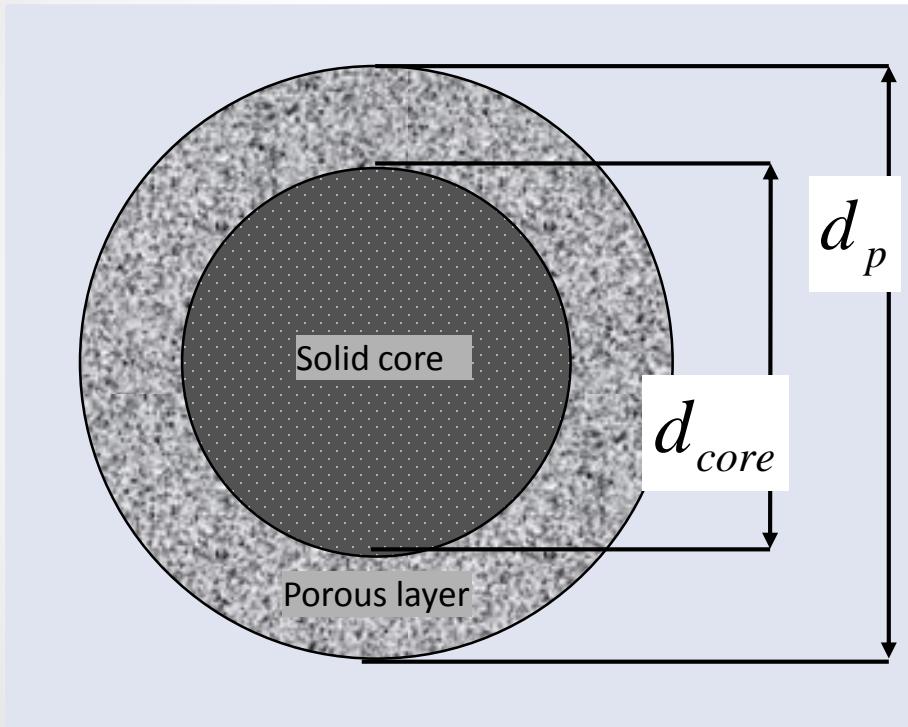

Figure and photo courtesy of Dr. Bill Barber, Agilent Technologies

# Morphology of Superficially Porous Particles

The porous volume fraction  $\varphi$  of a superficially porous particle is given by

$$\varphi_{PV} = 1 - \left( \frac{d_{core}}{d_p} \right)^3 \cong 0.75$$

The internal porosity  $\varepsilon_i$  of a superficially porous particle is assumed to be

$$\varepsilon_i = \varepsilon_{i, \text{fully porous}} \cdot \varphi_{V\text{porous}}$$

Table II: Superficially porous particle columns for reversed-phase chromatography and HILIC					
Product	Company	Particle Size ( $\mu\text{m}$ )	Pore Diameter ( $\text{\AA}$ )	Phases	Comments
Accucore	Thermo Fisher Scientific	2.6	80	C18, RP-MS, aQ, PFP, phenyl-hexyl, HILIC	Average particle size distribution (D90/D10): 1.12; column dimensions: 30–150 mm $\times$ 2.1, 3.0, and 4.6 mm; guard columns (10-mm length) available with separate holder, validation and method development kits available; custom columns available.
Aeris Peptide	Phenomenex	1.7, 3.6	100	C18 (for peptides)	For peptides; shell thickness (3.6- $\mu\text{m}$ particle): 0.5 $\mu\text{m}$ ; core diameter: 2.6- $\mu\text{m}$ ; shell thickness (1.6- $\mu\text{m}$ particle): 0.2 $\mu\text{m}$ ; core: 1.25 $\mu\text{m}$ ; column dimensions: 50–250 mm $\times$ 2.1 and 4.6 mm.
Aeris Wide Pore	Phenomenex	3.6	200	C4, C8, C18 (for polypeptides and proteins)	For polypeptides and proteins; shell: 0.2 $\mu\text{m}$ ; core: 3.2 $\mu\text{m}$ ; column dimensions: 50–250 mm $\times$ 2.1 and 4.6 mm.
Ascentis Express	Supelco/Sigma Aldrich	2.7	90	C8, C18, phenyl-hexyl, RP-Amide, PFP, HILIC, ES-Cyano, OH5 (HILIC)	Shell thickness: 0.5 $\mu\text{m}$ ; pore size: 90 $\text{\AA}$ ; pressure limit: 600 bar; dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm; capillary columns available
Ascentis Express	Supelco/Sigma Aldrich	2.7	160	Peptide ES-C18 (for peptides)	For peptides and polypeptides; shell thickness: 0.5 $\mu\text{m}$ ; 600 bar; dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm; capillary columns available
Brownlee SPP	PerkinElmer	2.7	90	C8, C18, phenyl-hexyl, RP-Amide, PFP, HILIC (Silica), ES-CN	Shell thickness: 0.5 $\mu\text{m}$ ; pressure limit: 600 bar; dimensions: 20–15 mm $\times$ 2.1, 3.0, and 4.6 mm; endcapped and nonendcapped phases; guard column holder and columns (5-mm lengths) available; sold in packs of three; ultralow extracolumn volume optimization kit available for instrument modification
Brownlee SPP	PerkinElmer	2.7	160	Peptide ES-C18 (for peptides)	For peptides or polypeptides; shell thickness: 0.5 $\mu\text{m}$ ; pressure limit: 600 bar; dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm.
Eiroshell	Irish Separation Science Cluster	1.7	100	C18 (not a commercial product)	Shell thickness: 0.35, 0.25, and 0.15 $\mu\text{m}$ ; these are research products and are not commercially available
Halo	Advanced Material Technology	2.7	90	C8, C18, phenyl-hexyl, RP-Amide, PFP, HILIC, ES-CN, penta HILIC (Pentanol functionality)	Shell thickness: 0.5 $\mu\text{m}$ ; pore size: 90 $\text{\AA}$ ; pressure limit: 600 bar; dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm; capillary columns available
Halo	Advanced Material Technology	2.7	160	Peptide ES-C18 (for peptides)	For peptides or polypeptides: shell thickness: 0.5 $\mu\text{m}$ ; pressure limit: 600 bar; dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm; capillary columns available
Kinetex	Phenomenex	1.7, 2.6	100	C8, C18, XB-C18 PFP	PFP = pentafluorophenyl; shell thickness: 0.35 $\mu\text{m}$ (2.6- $\mu\text{m}$ particle) and 0.23 $\mu\text{m}$ (1.7- $\mu\text{m}$ particle); pressure limit: 800 bar (2.6 $\mu\text{m}$ ), 1000 bar (1.7 $\mu\text{m}$ ); dimensions: 30–150 mm $\times$ 1.0, 2.1, 3.0, and 4.6 mm; capillary columns available
Nucleoshell	Macherey-Nagel	2.7	90	C18, PFP, HILIC	Shell thickness: 0.5 $\mu\text{m}$ ; core: 1.7 $\mu\text{m}$ ; column dimensions: 50–150 mm $\times$ 2–4.6 mm; maximum pressure: 600 bar; pH range: 1–11; multilendifcapped for improved peak shape with basic compounds; HILIC is zwitterionic ammonium-sulfonic acid phase
Poroshell 120	Agilent Technologies	2.7	120	SB-C18, EC-C18, EC C8, HILIC (silica)	Shell thickness: 0.50 $\mu\text{m}$ ; core diameter: 1.7 $\mu\text{m}$ ; pressure limit: 600 bar; column dimensions: 30–150 mm $\times$ 2.1, 3.0, and 4.6 mm; double endcapped and onendcapped phases.
Poroshell 300	Agilent Technologies	5.0	300	SB-C3, SB-C8, SB-C18, Extend (for proteins)	Extend = Bidentate C18, upper pH limit = 11; shell thickness: 0.25 $\mu\text{m}$ ; core diameter: 4.5 $\mu\text{m}$ ; pressure limit: 400 bar; column dimensions: 17 mm (guard for 1.0-mm), 12.5 mm (guard for 2.1-mm), and 75 mm $\times$ 0.5, 1.0, and 2.1 mm; capillary columns available
Sunshell	ChromaNIK Technologies	2.6	80	C18, C8, PFP	Shell thickness: 0.5 $\mu\text{m}$ ; core: 1.6 $\mu\text{m}$ ; pH limits: 1.5–10; endcapped; phase coverage C18: 7% carbon; average particle size distribution (D90/D10): 1.15; column dimensions: 20–150 mm $\times$ 2.1, 3.0, and 4.6 mm; marketed in UHPLC format

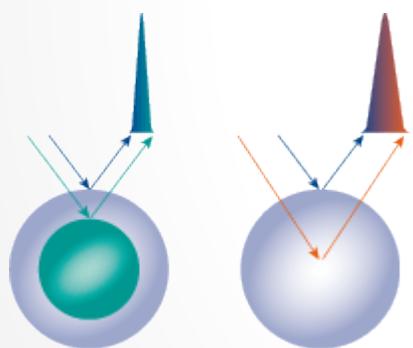

Bonshell, 2.7  $\mu\text{m}$ , 0.5  $\mu\text{m}$  porous shell  
**Bonna-Agela** Technologies, Wilmington, USA  
**Phenomenex**, 5  $\mu\text{m}$  Kinetex  
**Brownlee** (now Perkin Elmer) SPP columns

Table taken from : R. Majors, LCGC North America, Special Supplement on HPLC Column Technology, April, 2012

Columns packed with superficially porous particles will deliver significantly higher efficiencies than columns packed with totally porous particles of the same diameter\*

The shorter diffusion path of HALO® particles reduces axial dispersion of solutes and minimizes peak broadening. A Halo particle has only a 0.5 µm diffusion path compared to the approximately 1.5 µm diffusion path of a 3 µm totally porous particle. \*\*.

Benefits of core-shell technology particles vs. totally porous silica gel\*\*\*

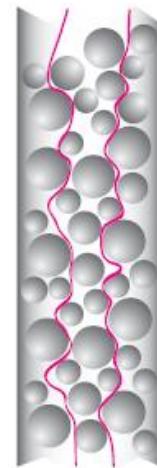

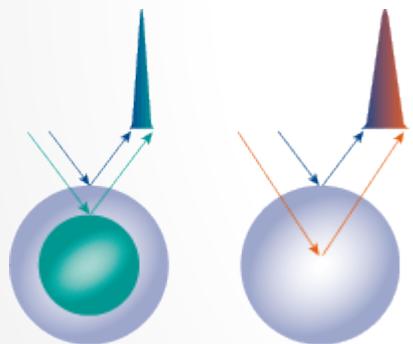

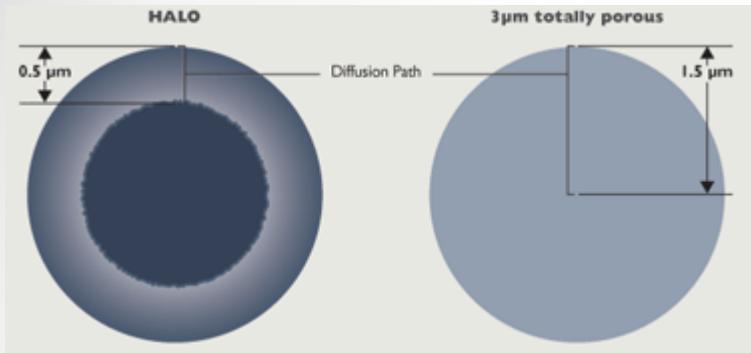

- Short diffusion paths resulting in fast mass transfer (C-term of van Deemter equation)
- Narrow particle size distribution ( $d_{90}/d_{10} \sim 1.1$ )

# HETP vs. $u$ according to Knox (and others)

## Knox Equation!

$$H = A \cdot d_p \cdot u^{0.33} + \frac{B \cdot D_m}{u} + C \cdot \frac{d_p^2}{D_m} \cdot u$$

A-term

B-term

C-term

## Knox Equation (reduced form)

$$h = A \cdot v^{0.33} + \frac{B}{v} + C \cdot v$$

$$h = H / d_p$$

$$v = \frac{u \cdot D_m}{d_p}$$

A-term:

describes the solvent velocity inequalities through the bed and depends on the particle size

B-term:

describes the influence of solute diffusivity and decreases with solvent velocity

C-term:

describes the mass transport in and out of the particles, depends on particle size and solute diffusivity and increases with solvent velocity

$$H = A \cdot d_p + \frac{B \cdot D_m}{u} + C \cdot \frac{d_p^2}{D_m} u$$

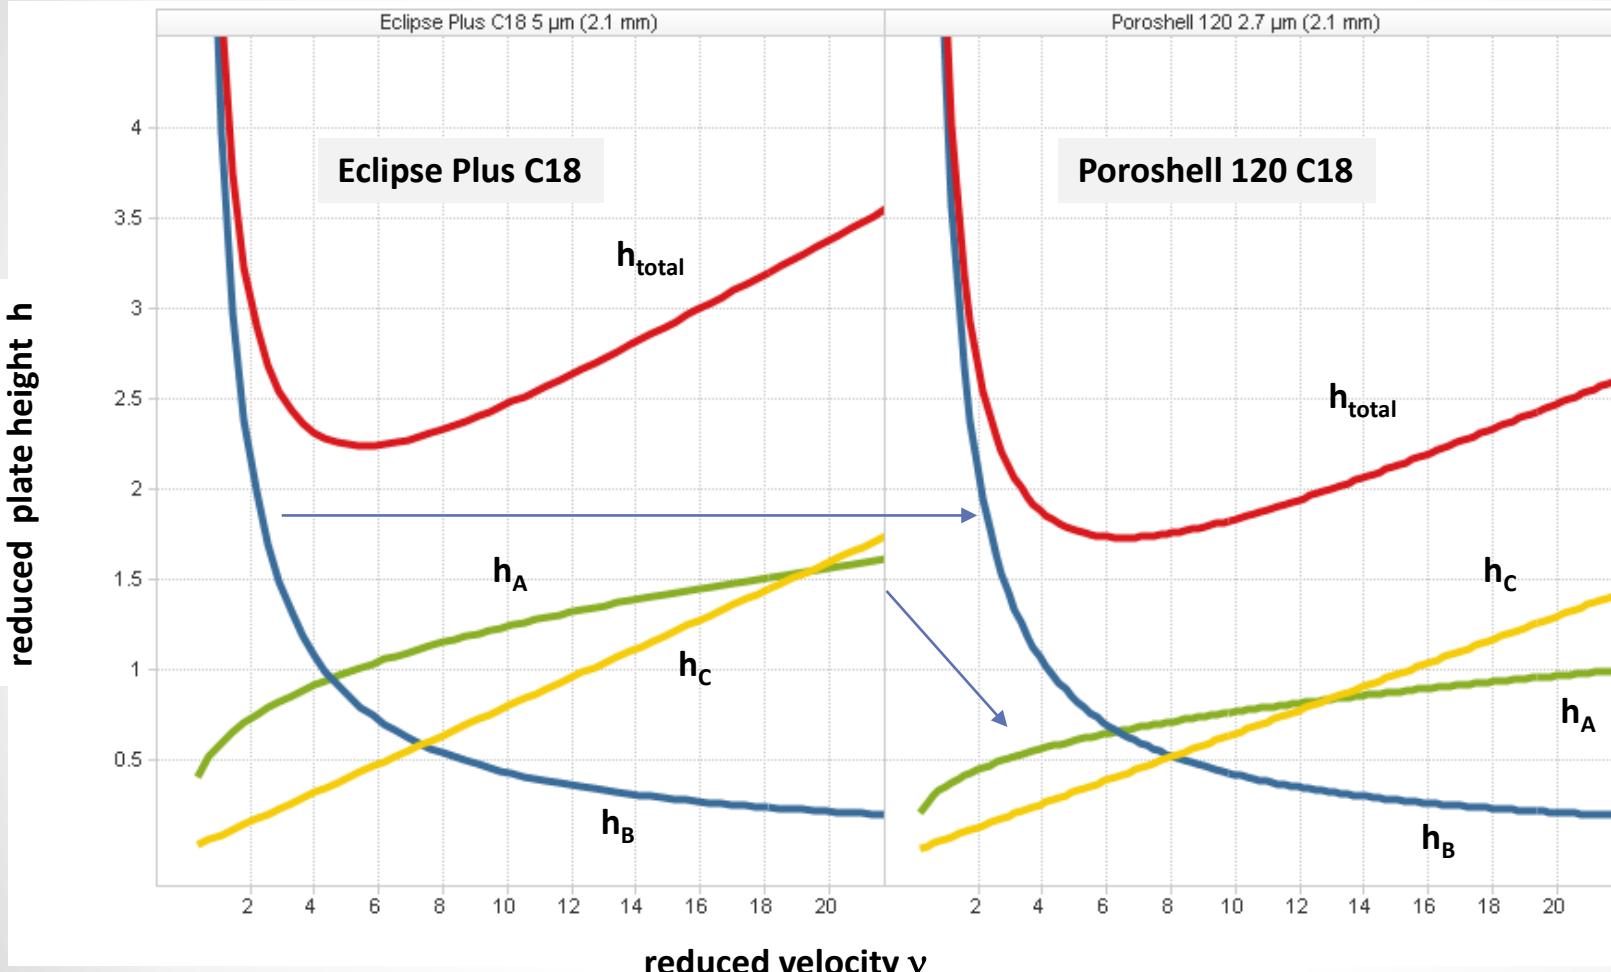

Van Deemter Equation

A-term

B-term

C-term

# Knox Plot TP and SP Particle Columns

$$h = H / d_p$$

$$\nu = \frac{u \cdot D_m}{d_p}$$

# Facts and Legends on Columns packed with sub-3 µm Porous Core-Shell Particles\*

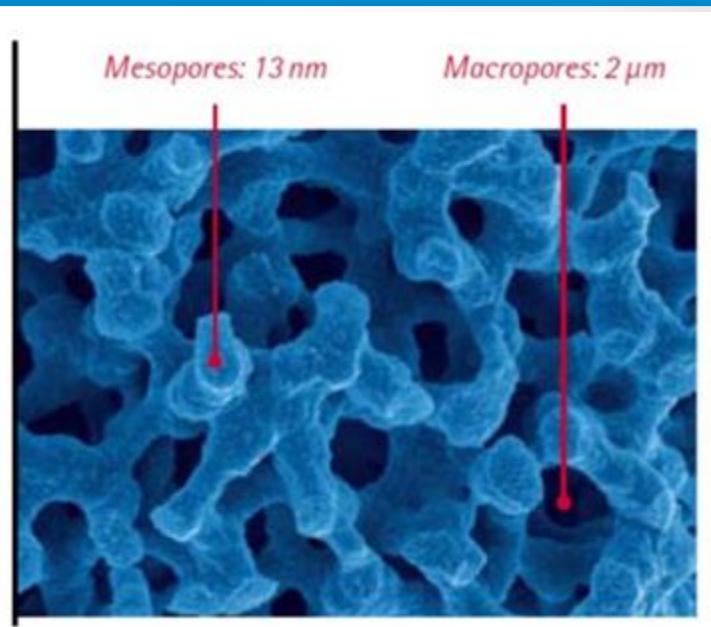

- The assumption that the shorter average diffusion path in SP particles leads to better performance (supplier brochures) is wrong
- In many explanations, the contribution of the B-term to the optimum HETP value (25%) is systematically neglected
- Also it is incorrectly assumed that the eddy dispersion term is independent of solvent velocity
- And it is incorrectly assumed that narrow particle size distribution leads to lower Eddy dispersion.

\*G. Guiochon & F. Gritti, LCGC North America, Vol. 30(7), 586 (2012)

# Monolithic Columns

## Pro's:

- High permeability → low backpressure
- Compatible with HPLC equipment
- Good efficiency esp. 2<sup>nd</sup> generation monoliths
- No column frit → high tolerance for “dirty” samples
- Good mechanical stability and longevity

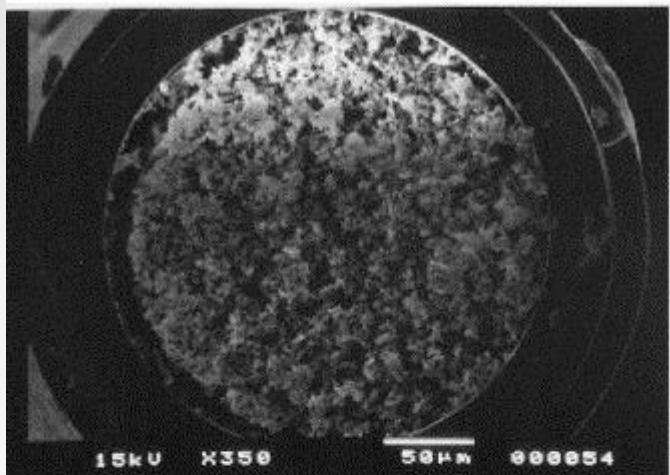

## Con's:

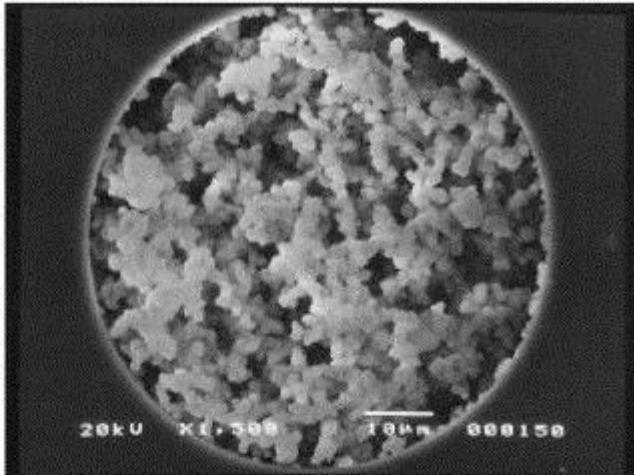

- Max. pressure 200 bar
- Few vendors
- Column to column reproducibility
- Polymeric monoliths lower performance than silica monoliths

# Monolithic Columns

## Poppe Plot comparison with particle column\*

Plots of plate time, ( $t_0 / N$ ), vs. plate number with particle-packed column and monolithic columns

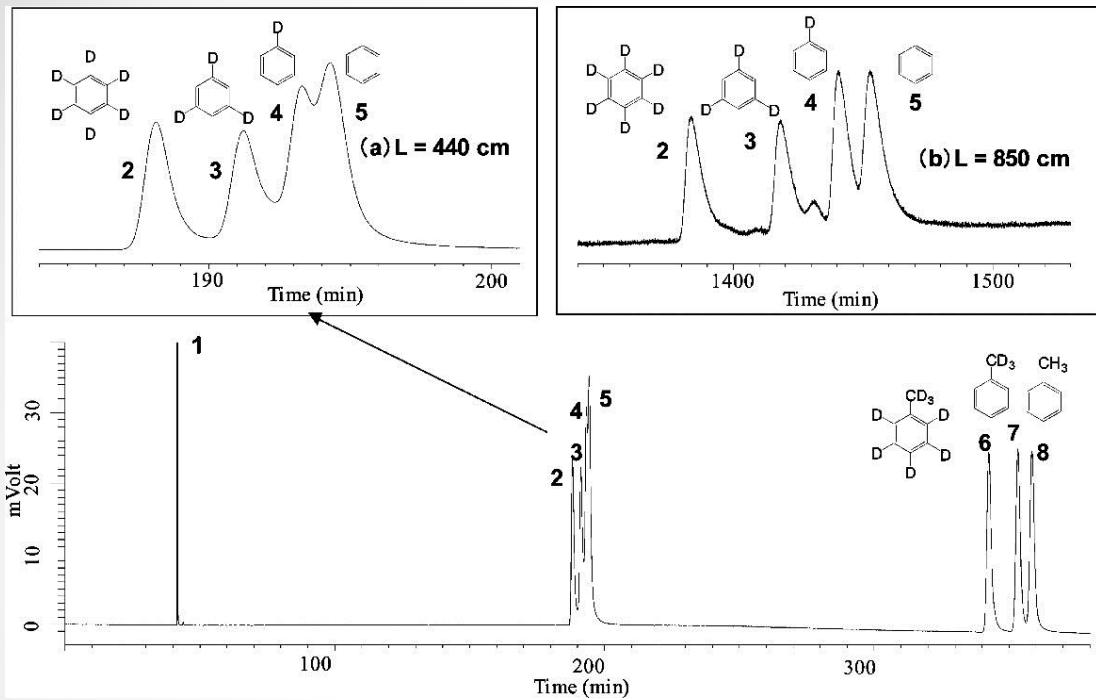

The curves for a column packed with particles were obtained by assuming the parameters, maximum pressure: 400 kg/cm<sup>2</sup>,  $\eta = 0.00047$  Pa / s,  $\phi = 1000$ ,  $D = 2.131029$  m<sup>2</sup>/s, and Knox equation

Particle diameter: (A) 1  $\mu\text{m}$ , (B) 2  $\mu\text{m}$ , (C) 5  $\mu\text{m}$ , (D) 10 mm. The points are based on the experimental results in 80% acetonitrile on a monolithic column, MS(50)-A (s), MS(50)-C (.), and a particle-packed column, Mightysil RP18 (d), extrapolated to the limiting conditions of 400 kg / cm<sup>2</sup>. The dashed lines indicate the required  $t_0$  values in seconds.

# Monolithic Columns

1.000.000 Plates!

\*Separation of styrene oligomers (molecular weight standard for MW = 580). The numbers in parentheses indicate the number of styrene units in the oligomer. Column: monolithic silica, effective length: 1130 cm. Mobile phase: acetonitrile–water (95/5).  $\Delta P = 39.5 \text{ MPa}$ .  $u = 1.73 \text{ mm/s}$ . Detection: 210 nm. Temperature: 30 °C. The inset is a magnification of the chromatogram for the pentamers.

\*Nobuo Tanaka et al., *Anal. Chem.* 2008, 80, 8741-8750.

# Lessons learned

## Superficially Porous Particles

- Superficially porous particles are an excellent compromise between efficiency of totally porous particles < 2 µm and permeability of larger particles (3 µm).
- The stationary phase volume of a SP particle is about 25% less than a totally porous particle
- The main reasons for the better efficiency of SP particle columns compared with TP particle columns are:
  - Lower contribution to HETP by Eddy dispersion (A-term)
  - B-term contribution is less since there is less volume in the particle
- Silica based monoliths have too large thru pores and therefore are more suited for very long columns for high plate number

# Method Translation

## HPLC → UHPLC Isocratic Separations

- Plate number scales linearly with length and inversely with particle size

$$N \sim \frac{L}{d_p}$$

Same time, better resolution  
Shorter time, same resolution  
Shorter time, lower resolution

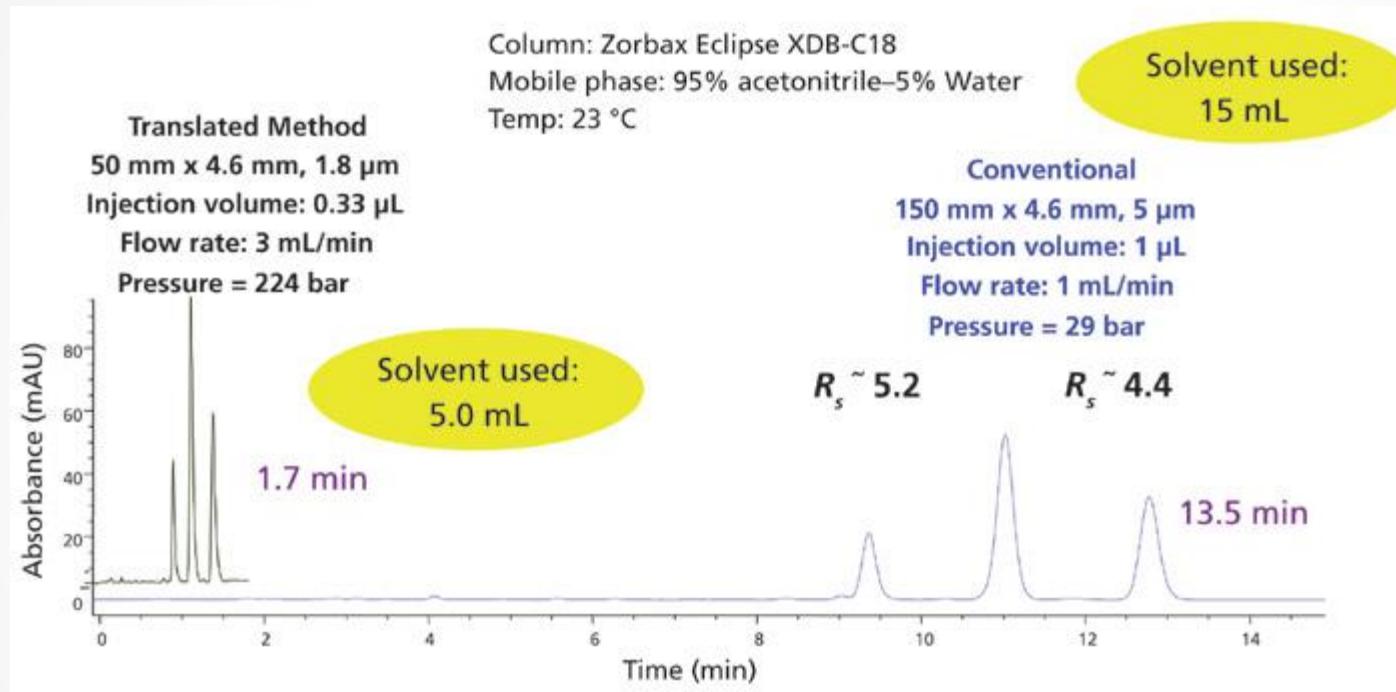

Column length (mm)	N, 5 µm	N, 3.5 µm	N, 1.8 µm
150	13050	18650	36250
100	8700	12400	24150
50	4350	6200	12100

- Flow rate scales quadratically with the column diameter

$$F_2 = \frac{d_{c2}^2}{d_{c1}^2} \cdot F_1 = \frac{2.1^2}{4.6^2} \cdot 1\text{mL/min} = 0.21\text{mL/min}$$

# Method Translation

HPLC → UHPLC Gradient Separations

# Method Translation

## HPLC → UHPLC Gradient Separations; definition of delay volume

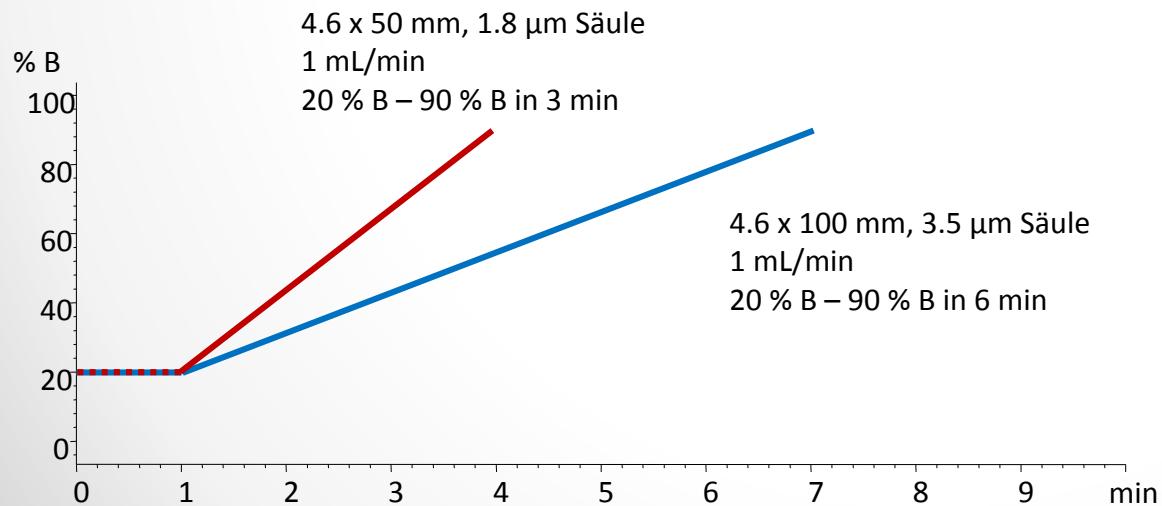

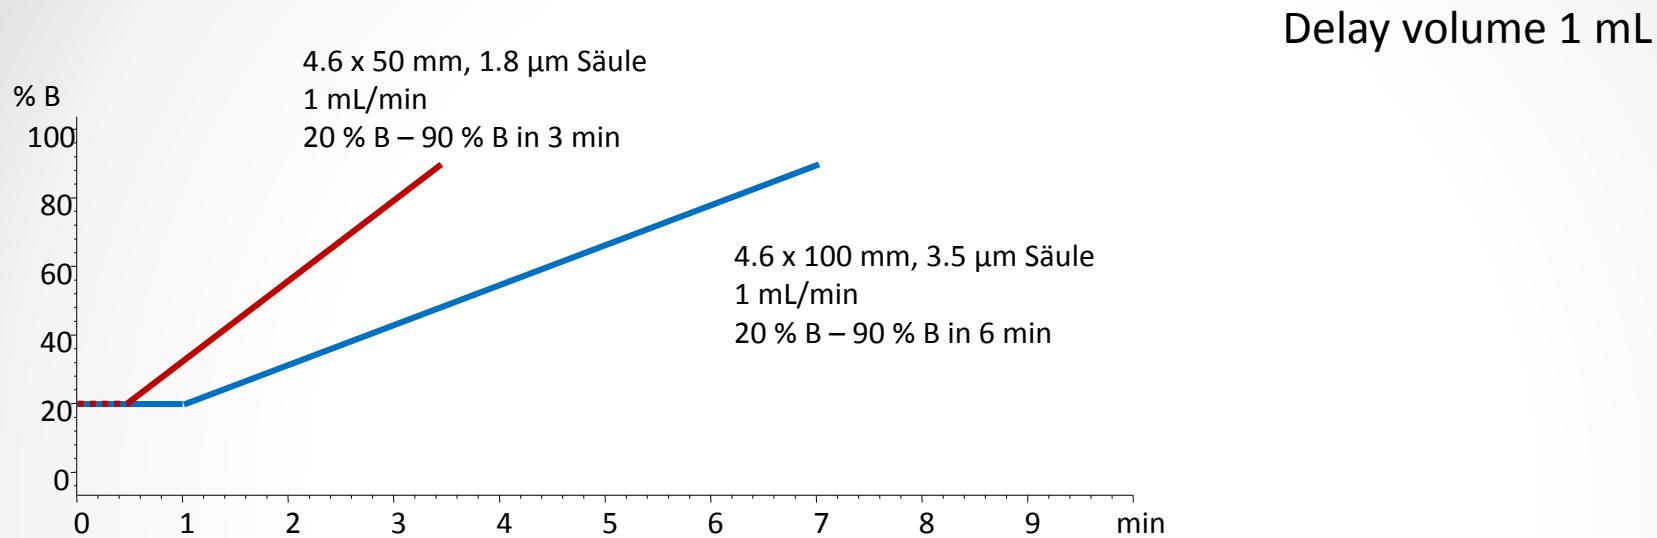

Delay volume or dwell volume defined as the “volume from the point of mobile phase mixing to the column head”

- Delays the arrival of the gradient at the head of the column
- Extends the time by which the solutes on the column are under isocratic separation conditions.
